

AIM: Renewable Energy Resources #4 and #5: GEOTHERMAL AND BIOMASS

Geothermal Energy

- Earth's internal heat is thermal energy generated from radioactive decay and continual heat loss from Earth's formation
- hot water and/or steam can be pumped up to **heat buildings** or used to spin a turbine to **generate electricity**

↑
more for individual residences
not in prime locations

↑
geothermal power plants in prime tectonic locations
– plate boundaries, hot spots, hot springs

| Pros of Geothermal Energy: | Cons of Geothermal Energy: |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <ol style="list-style-type: none"> 1 high efficiency 2 low land use/disturbance 3 abundant supply (both shallow and deep) | <ol style="list-style-type: none"> 1 specific prime locations (to generate electricity) 2 pump needs electricity - \$\$ (also a high upfront cost to install) 3 some noise... but major improvements have minimized this 4 gas release and land instability <ul style="list-style-type: none"> - H₂S can react to form SO₂ → acid rain - CH₄ and CO₂ (greenhouse gases) - earthquakes and land subsidence (sinking) |

Biomass is organic material that comes from plants and animals, and it is a renewable source of energy. Biomass contains stored energy from the Sun. Plants absorb the Sun's energy during photosynthesis and when biomass is burned, the chemical energy in biomass is released as heat.

Examples: plant material waste material biodiesel ethanol (ethyl alcohol from grains)
 (wood, crop residues) (manure/sewage/household) (vegetable oil/grease) (made from corn)

| Biomass Pros: | Biomass Cons: |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <ol style="list-style-type: none"> 1 large potential supply 2 helps reduce waste 3 "carbon neutral" no net carbon emissions since plants absorbed CO₂ while they were growing - only if sustainable forestry practices are used (replanting / no clear-cutting of forests) | <ol style="list-style-type: none"> 1 less efficient / less energy density 2 production can be more expensive (ex. ethanol) 3 environmental impacts <ul style="list-style-type: none"> - deforestation (leads to soil erosion and habitat destruction) - air pollution |
